

Recovery and Atomicity

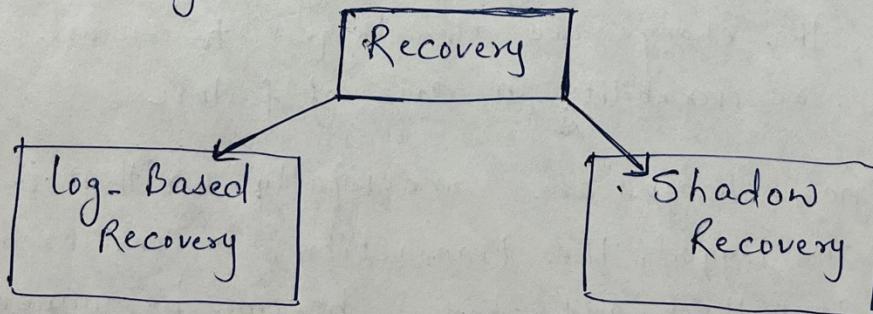

Recovery Procedure

i) Reexecute T_i : $\begin{array}{l} \text{Output}(B_A) = 900 \\ \text{Output}(B_B) = 2050 \end{array}$] Inconsistent

ii) Do not Reexecute T_i : $\begin{array}{l} A = 950 \\ B = 2000 \end{array}$] Consistent

So, Atomicity is our goal.

2) $\text{write}(X)$ assigns the value of local variable x_i to ~~the~~ data item X ~~to the local variable~~ in the buffer block. It executes this operation as follows:-

- If block B_x on which X resides is not in main memory, it issues $\text{input}(B_x)$.
- It assigns the value of x_i to X in buffer B_x .

Note

Block Movements between disk and main memory are initiated through the following two operations:-

- $\text{Input}(B)$ transfers the physical block B to main memory.
- $\text{Output}(B)$ transfers the buffer block B to the disk, and replaces the appropriate physical block there.

If the DBMS uses a logging mechanism for transaction management (e.g. write-ahead logging), the changes are also logged to ensure recoverability in case of failure.

- Once changes are successfully written to disk and logged, the transaction is considered committed, and changes become permanent.

Actual Process

- ① $\text{write}(A)$
- ② $\text{commit}(A)$ → logged
written
on disk
- ③ write to disk → data
permanent
on disk

Recovery System

RAID

Disk or Magnetic tapes are electromechanical] Non volatile

Volatile are mostly based on chips.

Page 643, 44

- 1) Read(X) assigns the value of data item X to the local variable x_i , and it executes this operations only as follows: —
 - a) if Block B_x on which X resides is not in the main memory, it issues input(B_x).
 - b) it assigns to x_i the value of X from the buffer block .
